Course and Year: BSIT-1 Section: IDA6

Self-Assessment:

Explain how "Awareness" in a shared workspace prevents two users from accidentally deleting each other's work.

Grading Rubric (5 Points)

Points	Rating	Description
5	Good	Clearly explains the role of <i>Presence Indicators</i> or <i>Telepointers</i> . Uses HCI terms like <i>Social Coordination</i> or <i>Edit Conflict</i> . Logic is sound and professional.
3	Fair	Explains that you can "see the other person," but lacks the technical terminology (Awareness, Synchronous interaction) to describe the mechanism.
1	Poor	Gives a very brief answer, like "You can see them so you don't click there," without explaining the HCI principle.
0	No Answer	No attempt made or the answer is irrelevant to shared workspaces.

Answer:

- *In a shared digital workspace, Awareness functions like a set of social cues that transform a static document into a live, inhabited room. By displaying real-time visual indicators such as a teammate's floating cursor, a highlighted text block, or a glowing avatar, the software provides immediate context about who is active and where they are focused. This transparency creates a natural boundary, similar to seeing someone's hand moving across a physical piece of paper, which instinctively signals you to avoid editing that specific area. By making every participant's presence visible, the system replaces guesswork with coordination, ensuring that users don't accidentally overwrite or delete a colleague's progress simply because they didn't know it was being worked on.*

Task Reflection

Summative Test

1. Identification: Name the cognitive principle that states users prefer to recognize things rather than remember them from scratch.

- **Recognition Rather Than Recall**

- *It emphasizes that the human brain can identify familiar objects, options, or actions much more easily than it can retrieve specific details from scratch. By making objects, actions, and options visible, designers minimize the user's memory load, making interfaces feel more straightforward and uncomplicated.*

2. C-E-R Analysis (Handwritten): "Should a design be based on what the designer thinks is 'cool' or what matches the user's 'Mental Model'?"

- Claim: Design must prioritize the user's Mental Model over what the designer considers "cool" to ensure the product is actually usable.
- Evidence: This approach prioritizes the management of Cognitive Load, which refers to the total amount of mental effort being used in the working memory.
- Reasoning: When a design matches a user's Mental Model, it reduces unnecessary Cognitive Load because the user doesn't have to "solve a puzzle" to find basic features. If a designer chooses a "cool" but unconventional layout, they force the user to waste mental energy learning new rules, which leads to fatigue and mistakes.

Task Reflection: Reflect on your experience during the "Ghost-Writing" activity. How did the presence of other users' cursors affect your "Planning" and "Decision-making" during the task?.

- Seeing other users' cursors felt like watching a live map of where my team was working. Instead of making a Strict Plan, I had to think and React to Movements as they happened. If I saw a cursor near a sentence I liked, I would decide to move to an empty spot to avoid getting in their way. This made our decision-making feel like a silent dance where we negotiated Space without talking. Even though it was a bit distracting, the cursors helped us coordinate and finish the story faster as a group.
